This article provides a beginners guide to what is known as the "crucc" car radio universal code calculator 2.4 17 with the hope that it might help those with no experience in this field. In today's ever more complex world of telecommunications, most systems require that each transmitter and receiver have a unique code assigned before they can communicate properly. This is done by assigning a numeric value to represent the transmitter and matching it with a second set of numbers representing the receiver - together they make up what is known as a "code". To give an example, one of the most common wireless communications systems for mobile phones uses four different frequency bands or ranges (called GSM bands). Each of these frequency bands is divided up into 256 "channels" and each channel number represents a unique 4-digit number. The problem is, how do you assign the codes, so that they are unique for each transmitter and receiver? If this was done manually, it would be very time consuming, tedious work for any large number of devices. The solution to this problem is the use of a computer programmed to rapidly generate "pseudo-random" numbers in sequence until it has exhausted every possible combination - then it repeats the sequence again. When it comes across a valid code combination that has not been used before, that code can then be assigned to any transmitter or receiver with another set of matching codes. The crucc car radio universal code calculator 2.4 17 made by the manufacturer "Crucc" works as follows: To start, a certain number of pre-determined combinations are programmed into the computer. For example: This will generate a sequence of 10 codes: The code calculator is then put into "search" mode. If we start with the code "100" and enter it, we get: Within this table, each of the 10 combinations listed in the previous section is assigned its own 4-digit decimal number. This decimal number can then be translated into letters or numbers by using a look-up table. For example: Now when searching for a specific car radio code, you can either use numbers, letters or both to make up your entry. For example: - click on this link to download the 2. 4 17 version in pdf format: The links to the original article in PDF format are: [1], [2], [3] and [4]. As seen above, this software developed by Crucc International Ltd. has many advantages for anyone with a good knowledge of computers to be able to work it. These include:

The crucc car radio universal code calculator 2.4 17 can either be connected to your computer via USB cable, or through the car radio; we personally we see them connected via an SD card (which is typically inserted into a slot on the back of most mobile phone models) and all the codes entered by the user will already be written onto that SD card.
